# Impact-area of an ejecta-ray from the Port Hedland Crater or from the VLC, located near Geraldton (Western Australia)

- Raman Spectra of selected Rock Samples - by Harry K. Hahn, 30.12.2021 -

#### Summary:

The visited area is located near the town Geraldton / Western Australia. The Gravity Anomaly Map indicates that Ejecta-material either from the assumed Ø 400 x 350 km Port Hedland Crater or from the Victoria Lake Crater (E-Africa) in all probability impacted here and formed these linear structures. The Port Hedland Crater is located north of the town Port Hedland on the sea-floor of the Indian Ocean. The Port Hedland Crater and the Victoria Lake Crater (VLC), which are both unknown craters yet, in all probability are large secondary craters that were caused by the Permian-Triassic Impact Event. For a detailed description of the Permian-Triassic Impact (PTI) Hypothesis please read Part 1 (P1) of my hypothesis. And for more information to the Ø 400 x 350 km Port Hedland Crater (PHC) please read pages 14-16, 20-21 and 24-28 of Part 3 (P3) and page 33 of Part 2 (P2) of my hypothesis.

The geological map shows large-scale structures that have strong similarities to structures caused by ejecta-blankets which were produced by an impact (  $\rightarrow$  see explanation in Part 3 (P3) on pages 24-28). These structures consist of rock types that are different to the rock types of the surrounding plains of the Yilgarn Craton. The nearly linear ejecta-ray structures seem to have penetrated the Yilgarn Craton approximately up to a depth of around 10 km (  $\rightarrow$  see geologic cross-section B-C on the geological map "Perenjori-sh6006).

I have collected some rock-samples from these nearly linear structures in the Geraldton area and have analysed these samples, mostly quartz, with Micro-Raman-Spectroscopy, to find out if they were exposed to a shock pressure which may indicate an Impact Event. And indeed that is the case!

The Raman-spectra of quartz from the Sample Sites 11, 12 and 17 provide first evidence for an impact event as the probable cause of the linear ray-structure in the visited area (→ map Detail 2). Indication for an impact shock event comes also from the sites 23 and 24. The clear shifts of the main Raman peaks, of the analysed quartz samples, to the lower frequencies 461 and 126 cm<sup>-1</sup> (Site 12, stone 1), to 463, 262/268 and 125 cm<sup>-1</sup> (Site 17, stone 1), to 463 and 125 cm<sup>-1</sup> (Site 11, stone 1), to 260/265, 125 cm<sup>-1</sup> (Site 17, stone 2) and to 261 and 126 cm<sup>-1</sup> (Site 12) provide first proof for an Impact Event as the cause of the ray-structure visible on a gravity-anomaly- and on a geological map! (→ see explanation in Appendix 1 at page 15: Overview: The Raman bands (peaks) of shocked Quartz)

The shifts of one main Raman peak, of analysed quartz grains from the sites 23 & 24, to the lower frequency 124 cm<sup>-1</sup> (Site 23) and to 261/263 cm<sup>-1</sup> (Site 24) may also indicate an impact shock event.

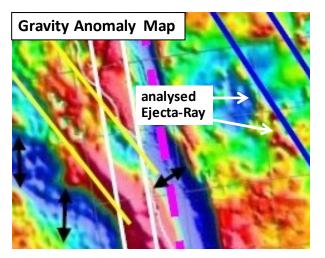

Microscopic images of some analysed quartz grains seem to provide further proof for a shock event.

PDFs (planar deformation features) seem to be present in some samples (→ images on pages 3 to 14)

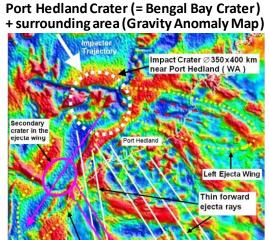

All spectra were made with a BRUKER Senterra-II Raman Microscope (wavenumber precision <0.1cm<sup>-1</sup>)

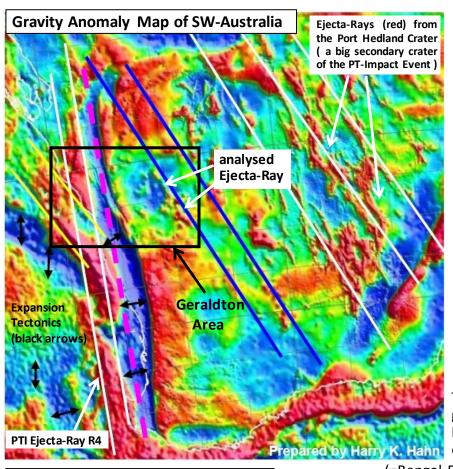

- → Images of the analysed rock samples and photos of the sample sites are in the Appendix at page 21.
- → More images of all sample sites are available on www.permiantriassic.de or www.permiantriassic.at
- → References: see page 22 / and pages 14-16, 20-21 and 24-28 of Part 3 (P3) of my hypothesis.

**Note:** A shock pressure of 20 GPa exceeds every pressure caused by normal terrestrial metamorphism. The indicated shock pressures of ≈20-22 GPa therefore in general point to an impact shock event.

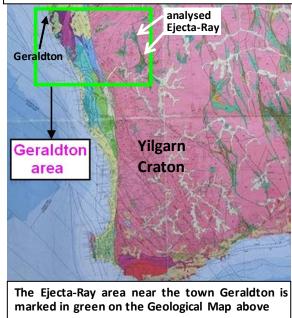

Ø 400 x 350 km Port Hedland Crater

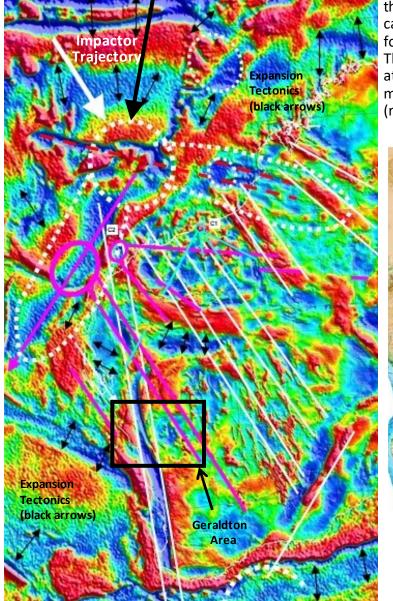

## Geological Map of South-West-Australia → with sample site area marked on the map

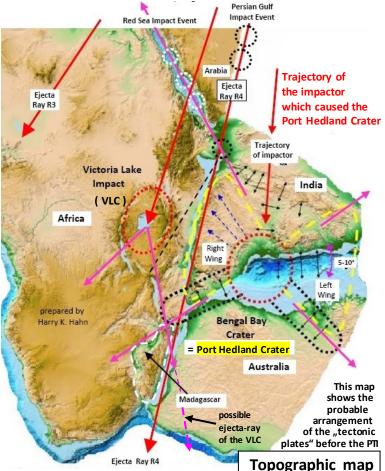

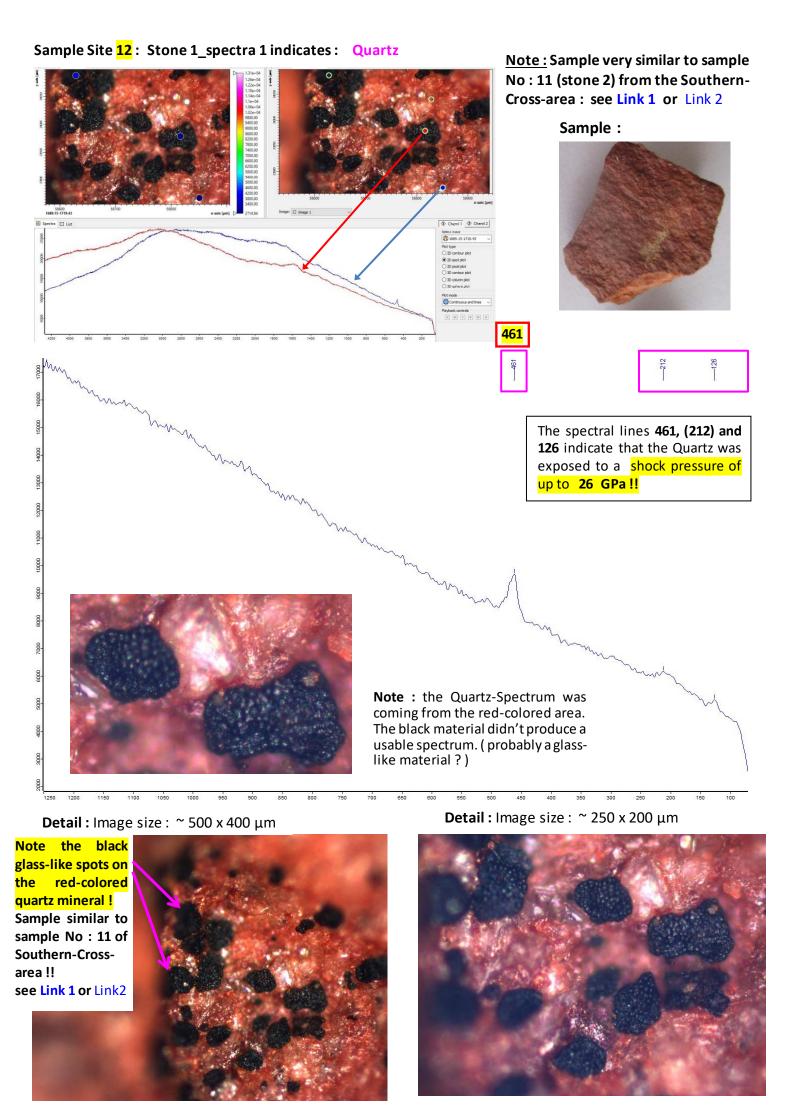

The thin ejecta-ray-structures visible on the gravity anomaly map of Western Australia as linear red (positive) anomalies, were caused either by the **Ø400x350km** Port Hedland Crater

(=Bengal Bay Crater) or by the Victoria Lake Impact Crater. According to my Permian-Trassic Impact (PTI) hypothesis the Port Hedland Crater (PHC) is a big secondary-crater caused by the **PT-Impact Event**, which is also responsible for the formation of the Bengal Bay (= Bengal Bay Crater) The topographic map below shows the original situation at the time of the PT-Impact Event. The gravity anomaly map indicates a number of linear eject-ray-structures (red) on the Yilgarn Craton which are (nearly) parallel

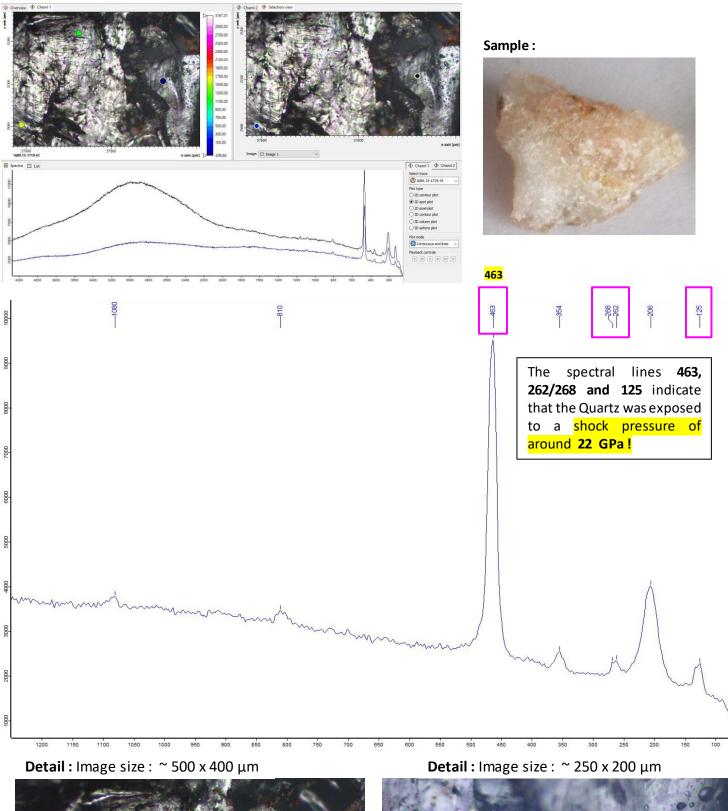

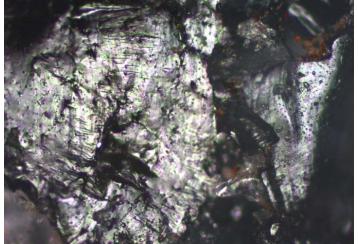

Ø 400x350 km Port Hedland Crater

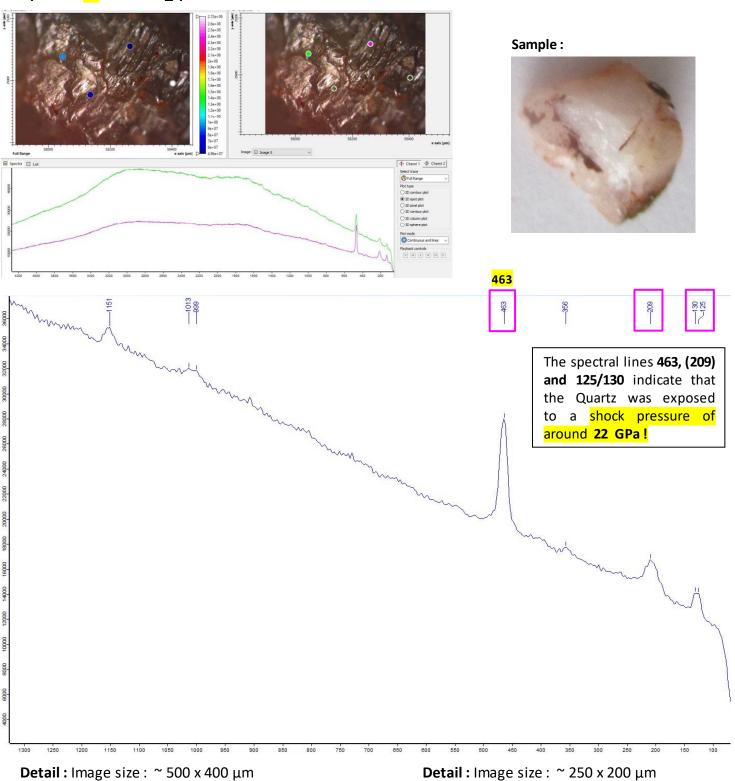

Sample Site 17: Stone 1\_spectra 1 indicates: Quartz

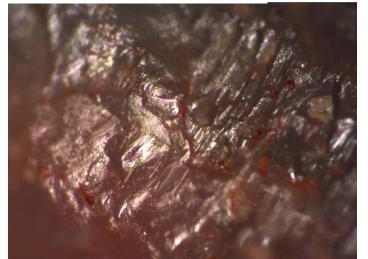

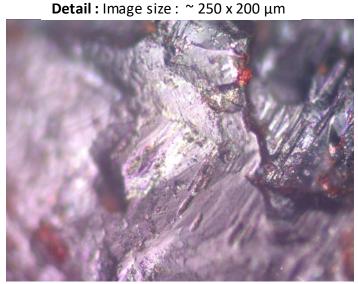

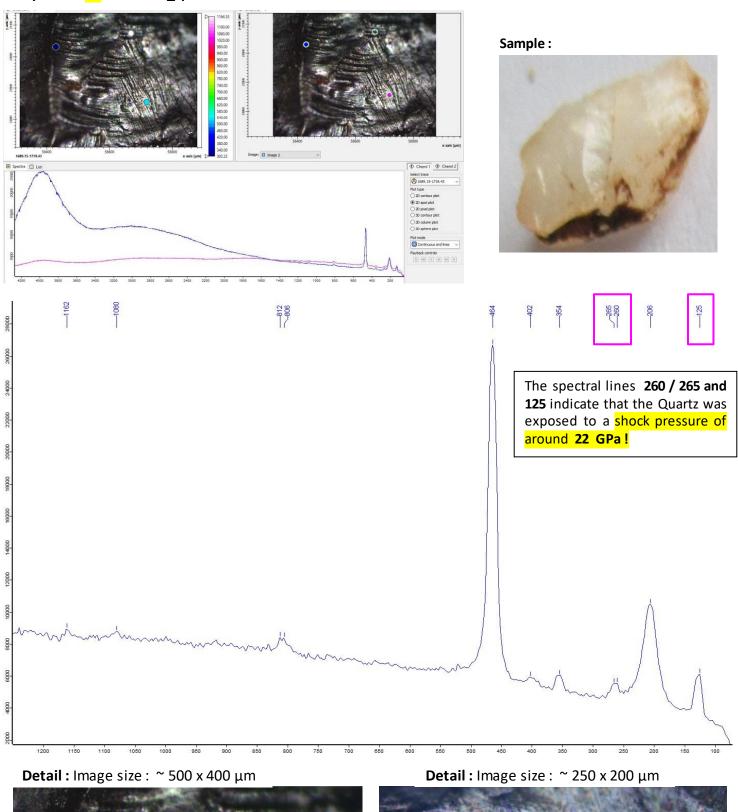

Sample Site 11: Stone 1\_spectra 1 indicates: Quartz

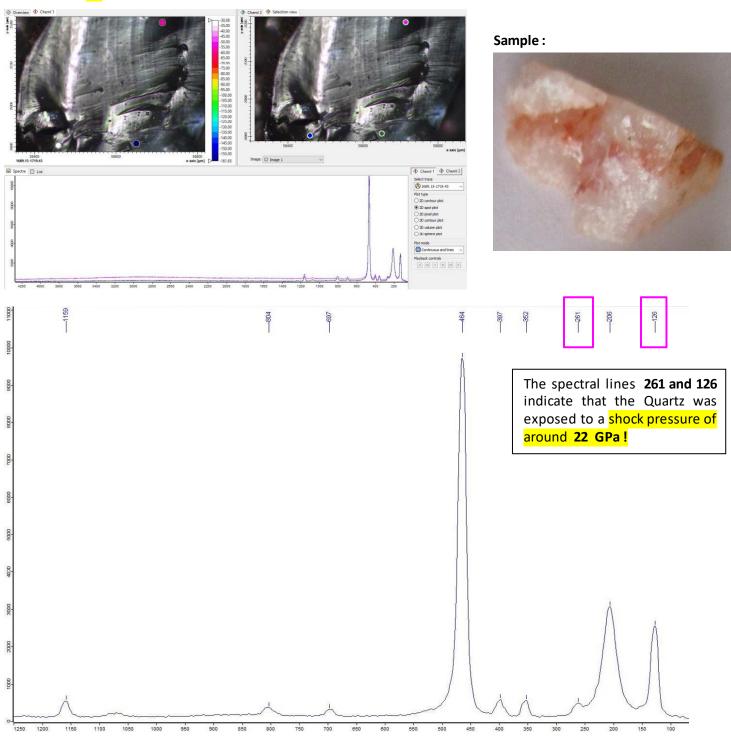

Sample Site 17: Stone 2\_spectra 1 indicates: Quartz

Sample Site 12: Stone 2\_spectra 1 indicates: Quartz

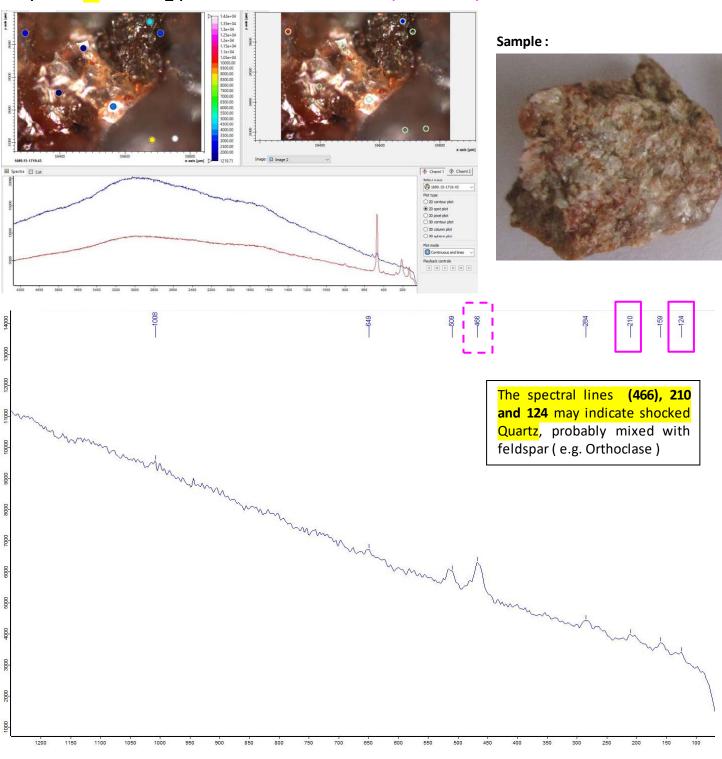

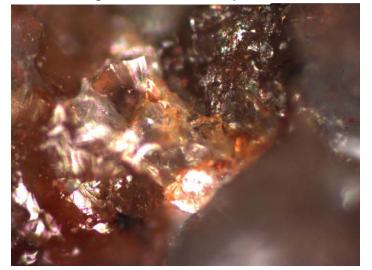

**Detail :** Image size :  $\sim$  250 x 200  $\mu$ m

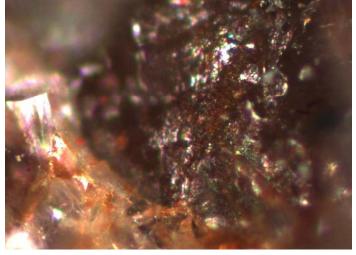

Sample Site 23: Stone 1\_spectra 1 indicates: Quartz + (Orthoclase)

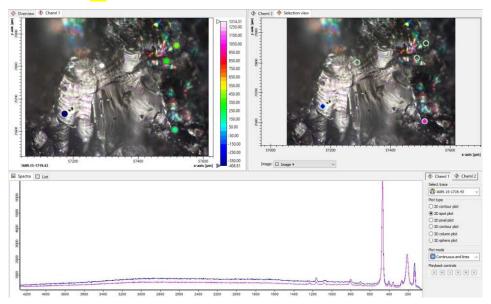

**Detail :** Image size :  $\sim 500 \times 400 \mu m$ 

**Detail :** Image size : ~ 250 x 200 μm

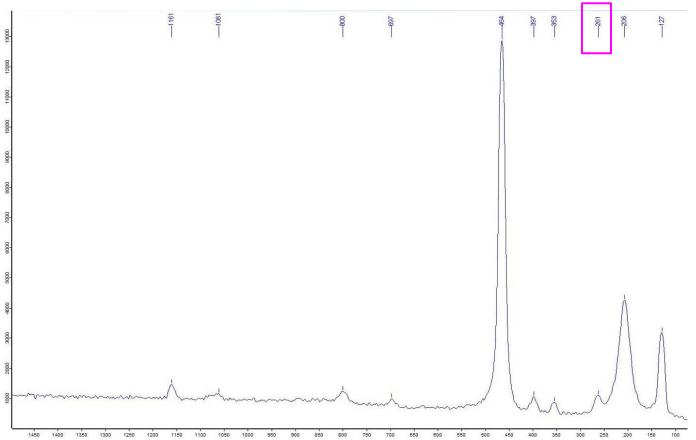

Sample Site 24: Stone 1\_spectra 1 indicates: Quartz

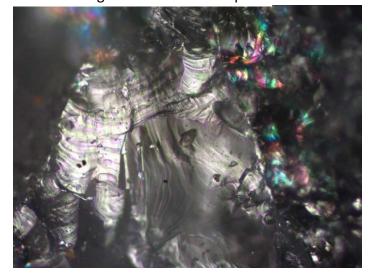

Sample:

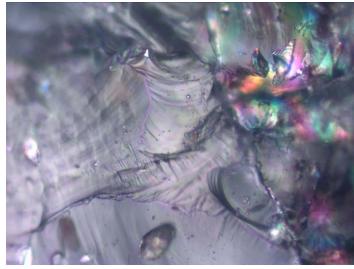

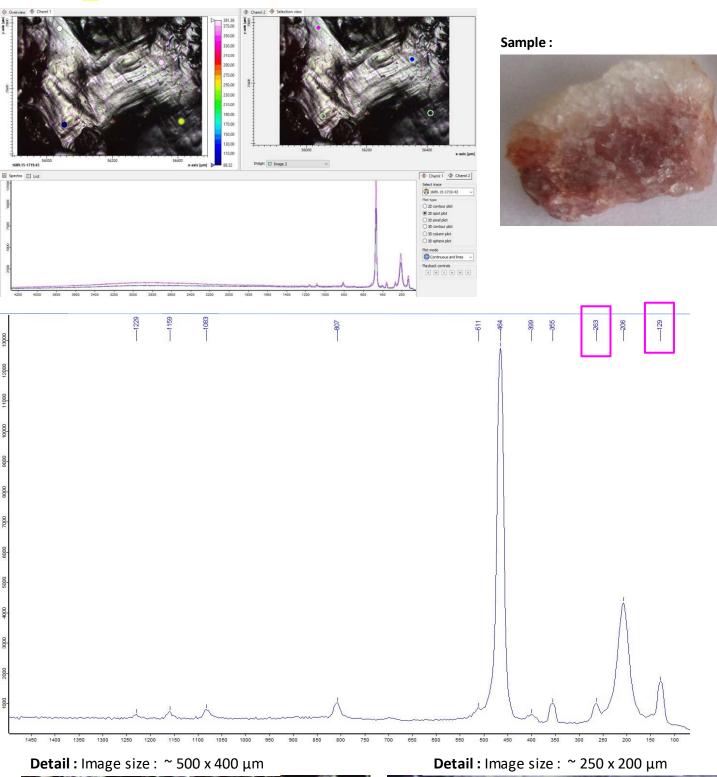

**Detail :** Image size :  $\sim 500 \text{ x } 400 \text{ } \mu\text{m}$ 

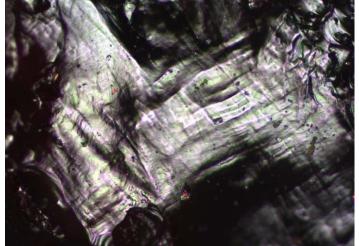

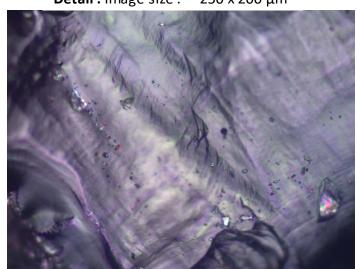

Detail: Image size: ~ 250 x 200 μm

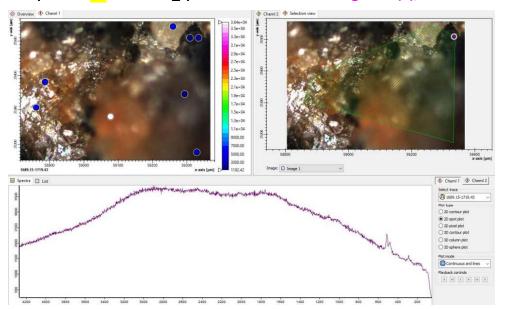

Sample Site 24: Stone 2\_spectra 1 indicates: Quartz

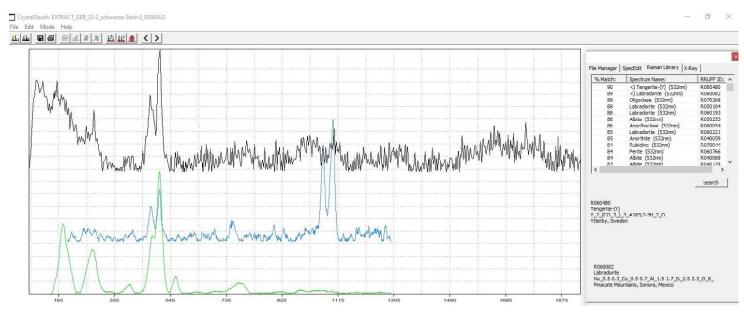

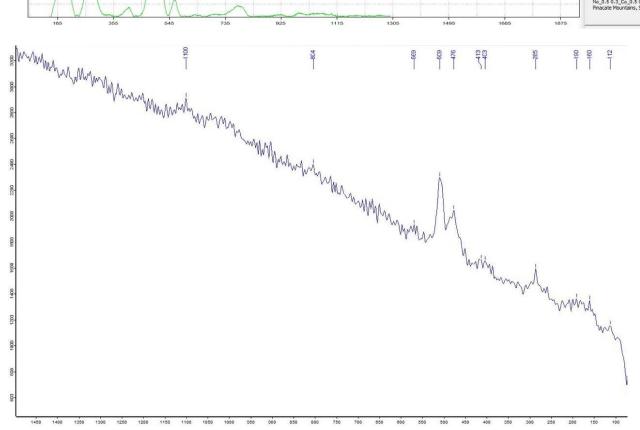

Sample Site 23: Stone 2\_spectra 1 indicates: Tengerite-(Y), Labradorite

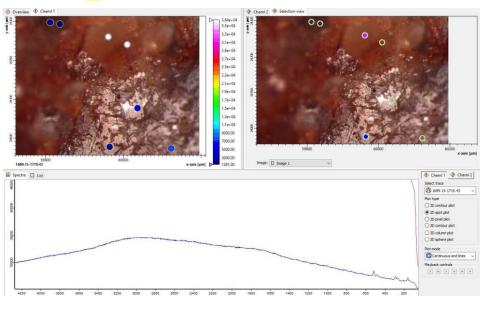

#### Sample:

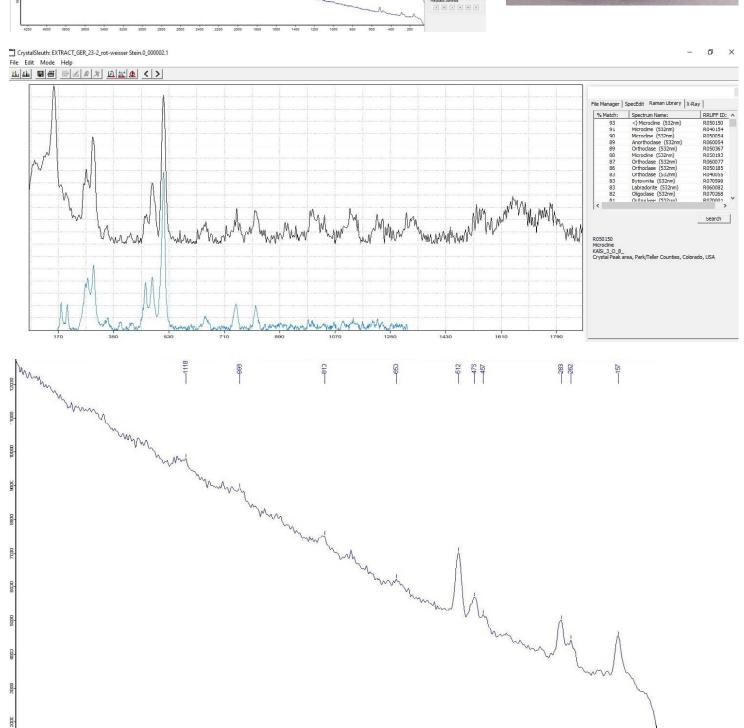

Sample Site 23: Stone 3\_spectra 1 indicates: Microcline

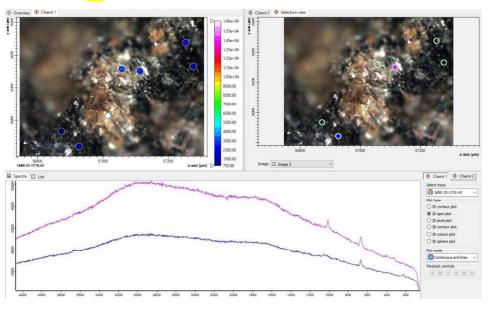

#### Sample:

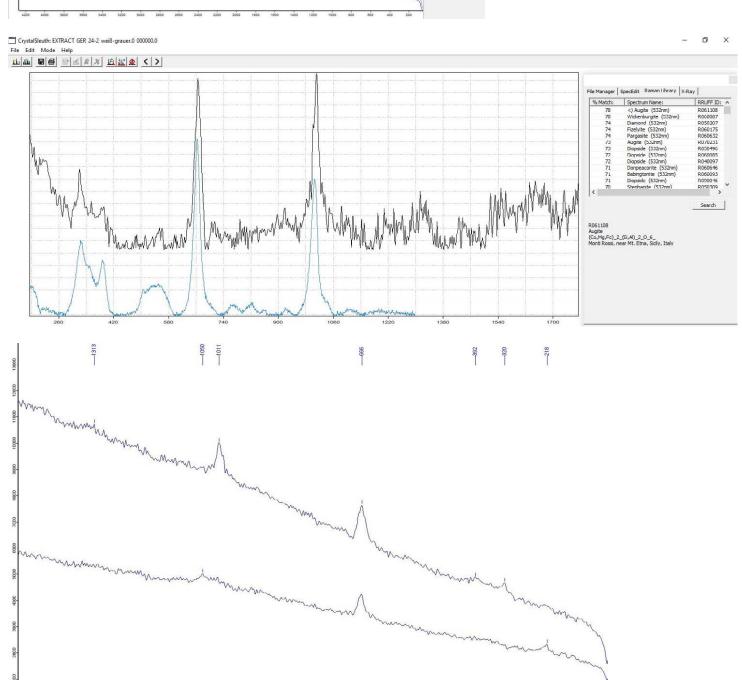

Sample Site 24: Stone 3\_spectra 1 indicates: Augite

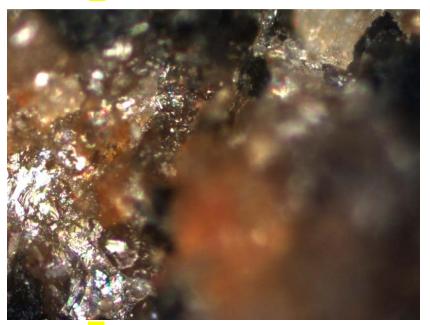

#### Sample:

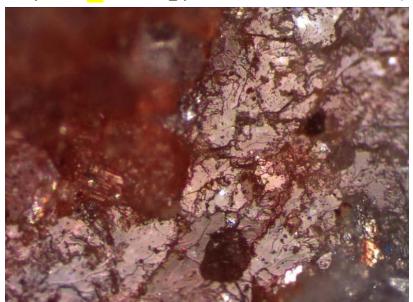

Microscopic Images : Sample from Site 23 and 24 → original state (no preparation for analysis)

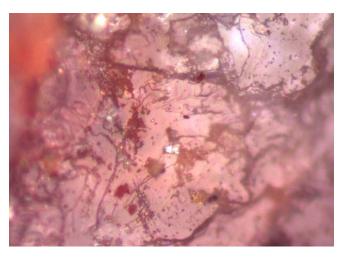

Sample Site 23: Stone 2\_spectra 1 indicates: Tengerite-(Y), Labradorite (Image ~ 500 x 400 μm)

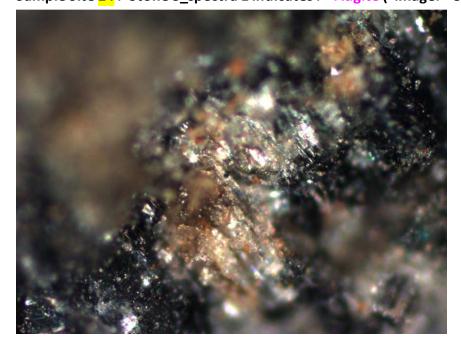

Sample Site 23: Stone 3\_spectra 1 indicates: Microcline (Image ~ 500 x 400 μm)

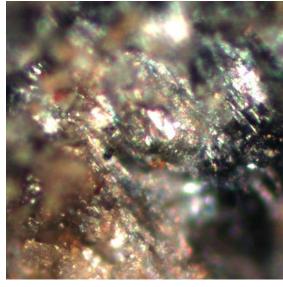

**Detail :** Image size :  $\sim$  170 x 130  $\mu m$ 

Sample Site 24: Stone 3\_spectra 1 indicates: Augite (Image: ~ 500 x 400 μm)

**Detail:** Image size: ~ 200 x 200 μm

#### Appendix 2: A short overview: The Raman bands (peaks) of Quartz shocked with 22-26 GPa

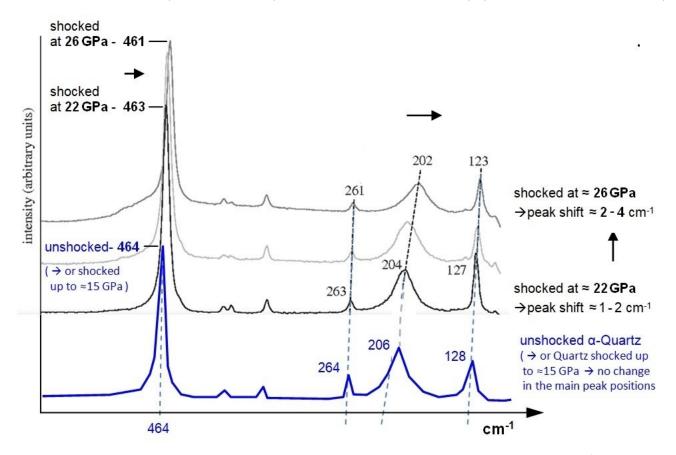

In order to verify a sample site as an impact site or impact structure, shock-metamorphic effects must be discovered in the rocks of the sample site. This can be done by different methods.

For example with the help of PDFs (planar deformation features) which are visible in the quartz with the help of a microscope. However this requires careful preparation of the samples and expertise.

Another, easier method, is the use of a RAMAN microscope. Micro-RAMAN Spectroscopy on quartz grains in the samples can provide the first evidence for a shock event, that was caused by an impact.

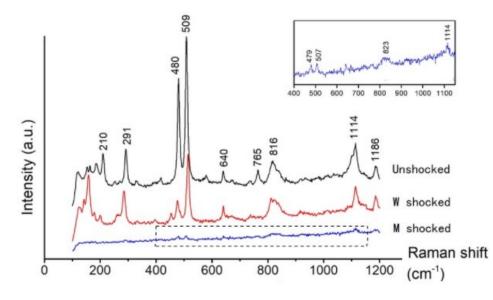

Mc Millan et al. (1992) and others have shown that the main RAMAN-peaks of Quartz shift towards lower frequencies if the Quartz was exposed the a shock-pressure > 15 GPa.  $\rightarrow$  see diagram below

The shift of the main quartz RAMAN-peaks can be used to identify quartz that was shocked by an impact

Quartz shocked with 22 GPa and 26 GPA shows shifts of the main RAMAN-peaks of 1 - 4 cm<sup>-1</sup> to lower frequencies

Appendix 3: Raman spectra of (W) weakly-shocked & (M) moderately-shocked Alkali-Feldspar

Weakly shocked alkali feldspar mainly developed irregular fractures and undulatory extinction. Note that the Raman-lines 210 and 765 are missing in the w-shocked feldspar, and an additional line at ≈ 150 appears.

The shock pressure for the w-shocked feldspar was estimated to be between 5 and 14 GPa
