

The Ø 160 km “Salerno Crater” (Italy)

- RAMAN Spectra of selected Rock Samples - by Harry K. Hahn, 30.6.2021 -

Summary :

Raman spectra of quartz samples collected at sample site **21** near Ascea on the west-coast of Italy (near Sapri) provide first indication for the Ø 160 km Salerno Impact Crater described in my hypothesis. The yet unknown Ø 160 km “Salerno Crater” belongs to a larger Secondary Impact Crater Chain, which was caused by impacting ejecta material that was ejected by the Ø 1270 x 950 km Permian Triassic Impact Crater (PTI), located in the Arctic Sea near Alaska, according to my hypothesis.

(→ weblink to my Permian Triassic Impact Hypothesis : → [Part 1 \(P1\)](#), [Part 2 \(P2\)](#) of my hypothesis)

The samples which I collected to proof the “Salerno Crater” did not provide the same clear evidence for a secondary impact crater, as for example the samples from Cabo de Creus in Spain, which provided solid evidence for the **130 x 110 km „Bay-of-Lyon Impact Crater“** ([Link2](#)), that belongs to the same Secondary Impact Crater Chain as the “Salerno Crater”, caused by the PT Impact-Event.

But the Raman spectra of quartz from sample site **21** at least provide first indication for a shock event.

The shifts of the main Raman bands (peaks) to the lower frequencies **261, 204 and 125 cm⁻¹** (Stone 1) and to **260 and 205 cm⁻¹** (Stone 2) which are visible in the Raman Spectra of these quartz-samples from sample site **21** at least give a first indication that the quartz was exposed to a **shock pressure in the range of 20 - 22 GPa**. The shock pressure probably was just below the treshold of 22 GPa so that the main quartz line at 464 didn't shift to a lower frequency (→ see explanation in the Appendix at page **28**)

Quartz in the samples from the sample site **20** also show shifts in one or two of the main Raman bands (peaks) to the lower frequencies **263 and 205 cm⁻¹**. The microscopic images of some of the analysed quartz grains in samples from site **21** & **20** may provide further proof for a shock event caused by an impact (see [page 5 & 6](#)). The images show complex micro-fracture-patterns in the analysed quartz grains. The spectra were made with a **BRUKER Senterra-II Raman Microscope** (wavenumber precision <0.1cm⁻¹)

In order to really verify the sample sites **20** and **21** as sites which were effected by an impact event and which are part of the described “Salerno Crater” clear shock-metamorphic effects must be discovered in the rocks of these sample sites. This can be done with the help of PDFs (planar deformation features) However this requires careful preparation of the samples and experience in PDF-analysis.

Therefore I want to ask scientists who read my studies to organize a professional analysis of samples from the center-area of the “Salerno Crater” in order to proof it as a secondary crater of the Permian Triassic Impact Event as described in my hypothesis.

A shock pressure of 20 GPa far exceeds every pressure caused by normal terrestrial metamorphism. The indicated shock pressure of ≈20 GPa is lower than the shock pressure that occurred in other large impact craters on Earth. This indicates that the “Salerno Crater” was caused by an oblique impact, and that the impactor which formed the crater (→ ejecta of the PT-Crater) impacted with low velocity <8 km/s

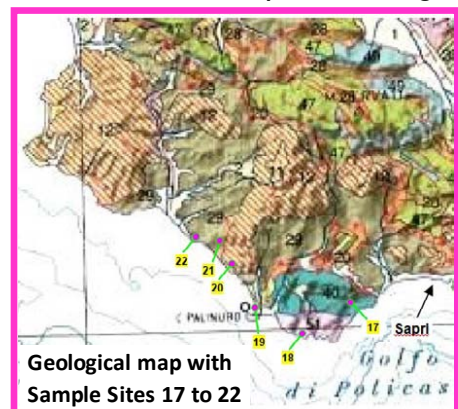

→ Images of the analysed rock samples and photos of the sample sites are in the Appendix at [page 24](#).

→ A general summary to all analysed sample sites is provided by [Part 6 \(P6\)](#) of my [PTI-hypothesis \(P1\)](#)

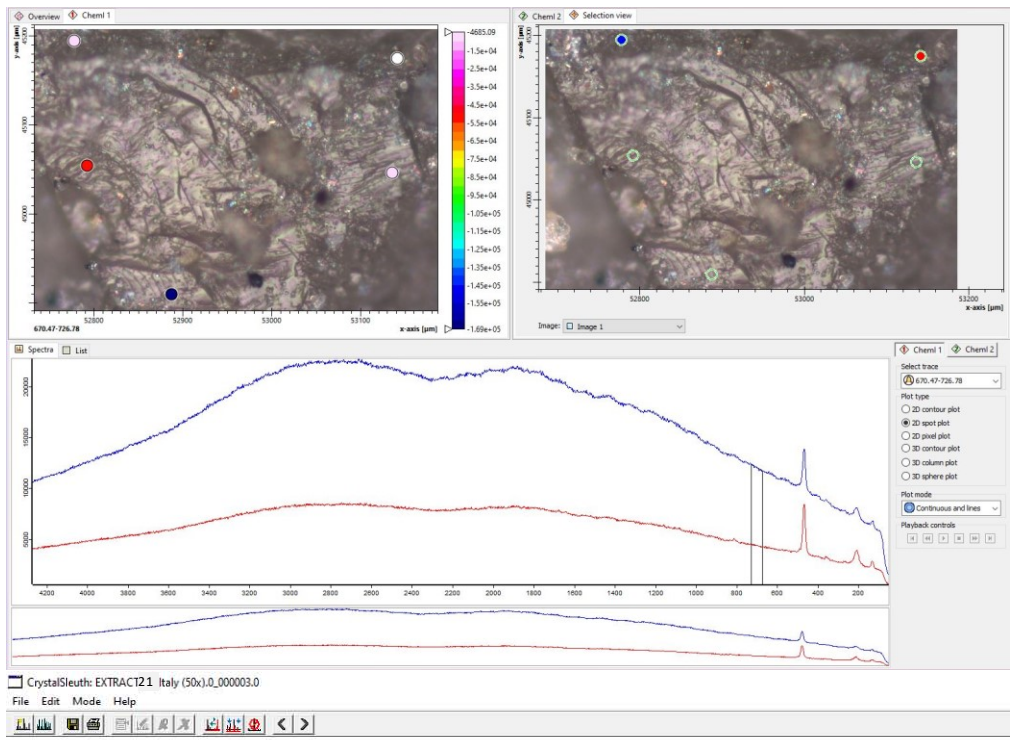

→ More images of all sample sites are available on www.permiantriassic.de or www.permiantriassic.at

The manipulated topographic map on the left shows the probable position of the crust fragments which form Italy at the time of the P/T-Impact 253 Ma ago

Sample Site **21** : Stone 1_spectra 1 indicates: **Quartz** (→ see RRUFF_CS results)

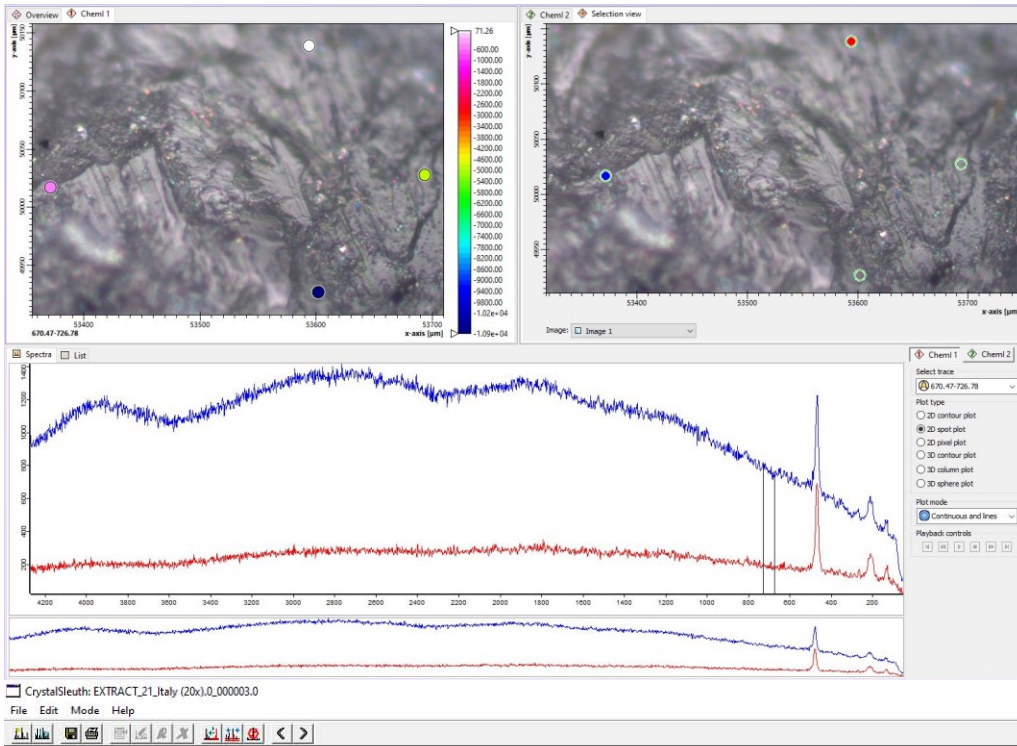

Sample :

Indication for a shock event are the shifts of the marked Quartz spectral lines towards 261, 204 and 125

Sample-Site **21** : Stone 2_spectra 1 indicates : **Quartz** (→ see RRUFF_CS results)

Sample :

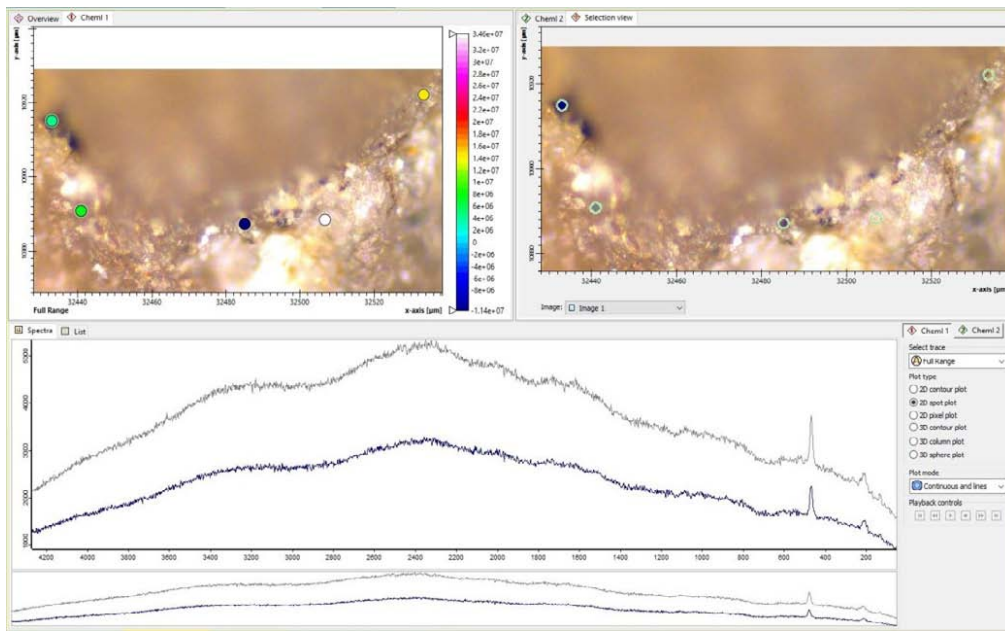

Indication for a shock event are the shifts of the marked Quartz spectral lines towards 260 and 205

The spectral lines 260 and 205 indicate that the Quartz was exposed to a shock pressure of around 20 - 22 GPa.

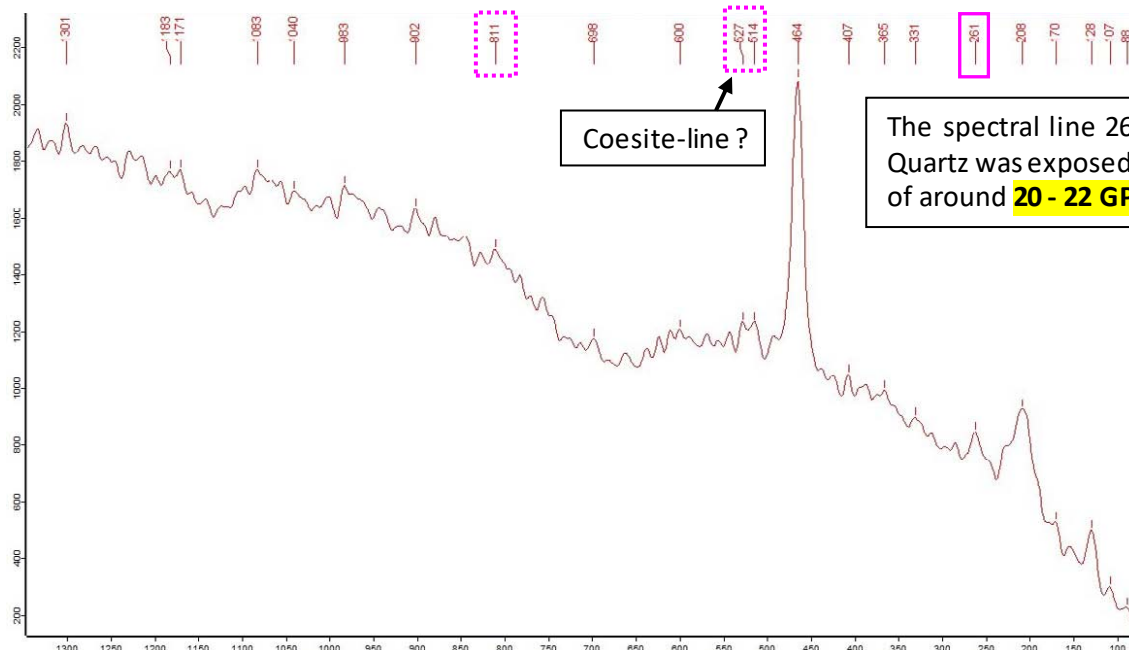

Sample Site **21**: Stone 2_spectra 2 indicates: **Quartz** (→ see RRUFF_CS results)

Sample:

Indication for a shock event is the shift of the marked Quartz spectral line towards 261

Coesite-line ?

The spectral line 261 indicates that the Quartz was exposed to a shock pressure of around **20 - 22 GPa**.

Microscopic Images : Sample from Site 21 → original state (no preparation for analysis)

Sample Site 21 : Stone 2_spectra 1 : Quartz - Image size : ~ 400 x 250 μm

Sample Site 21 : Stone 2 : Quartz - Image size : ~ 400 x 300 μm

Microscopic Images : Sample from Site 21 → original state (no preparation for analysis)

Sample Site 21 : Stone 1_spectra 1 : Quartz - Image size : ~ 400 x 300 μm

Sample Site 21 : Stone 1_spectra 2 : Quartz - Image size : ~ 250 x 200 μm

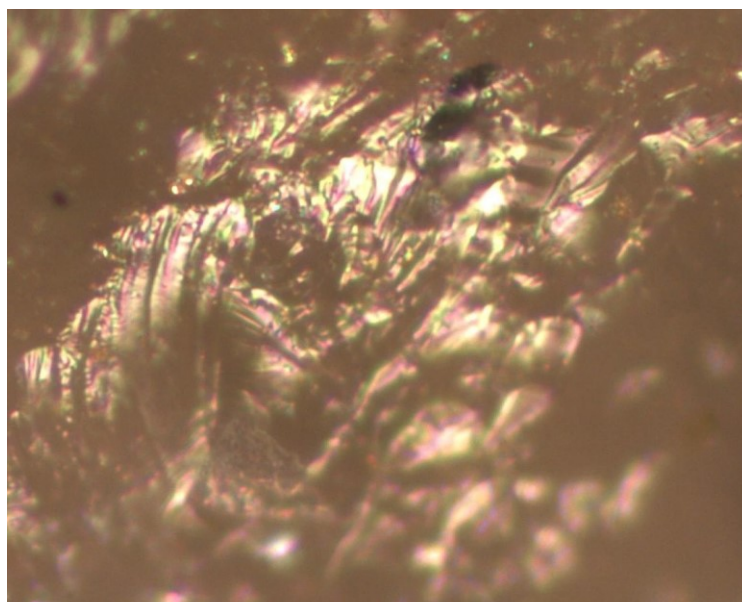

Sample Site 21 : Stone 1 : Quartz

Image size : ~ 200 x 180 μm

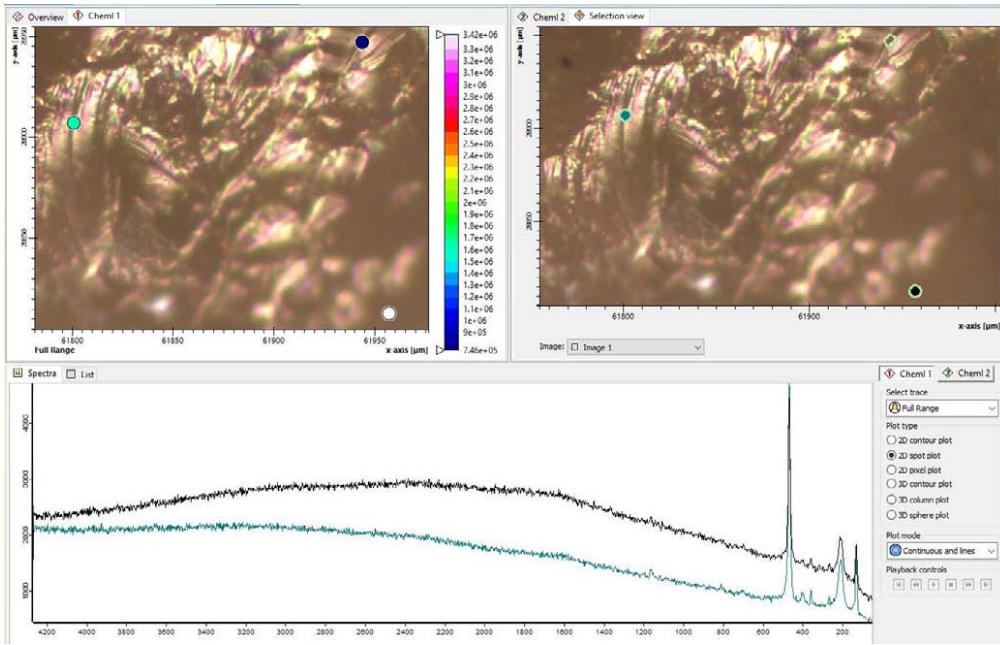

Sample Site 21 : Stone 3 : Quartz

Image size : ~ 220 x 200 μm

Sample-Site **21**: Stone 3_spectra 1 (crystal inclusion) indicates: **Quartz** (→ see RRUFF_CS results)

Sample :

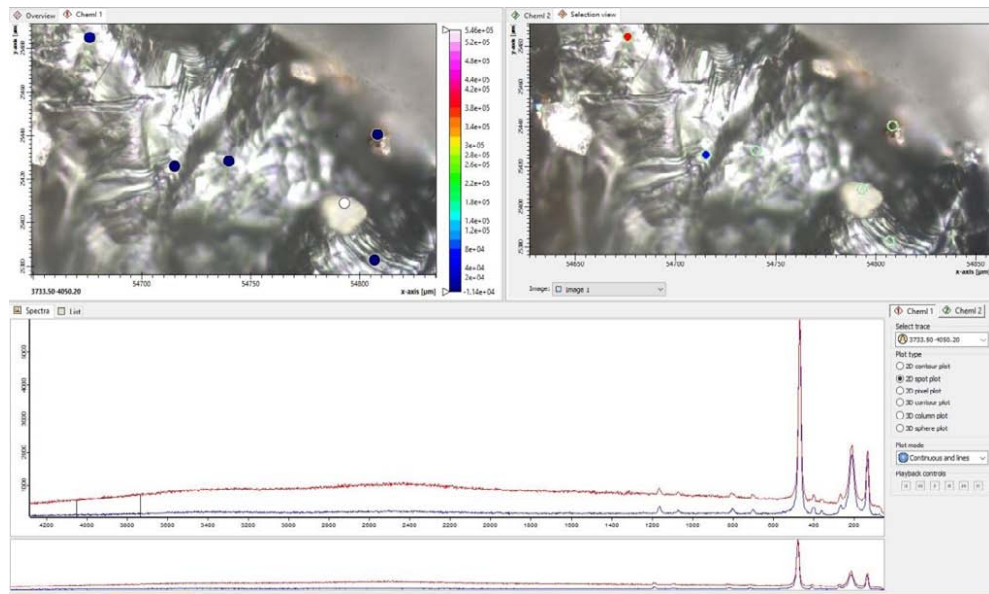

Indication for a shock event are the shifts of the marked Quartz spectral lines towards 261 and 201 (209)

The spectral lines 261 and 201 (209) indicate that the Quartz was exposed to a shock pressure of around 20 - 22 GPa.

Sample Site **21**: Stone 1_spectra 2 indicates: **Quartz Sugilite, Dachiardite-Na** (→ see RRUFF_CS results)

The spectral lines indicate that **Quartz** is the most probable mineral measured in this spectral analysis

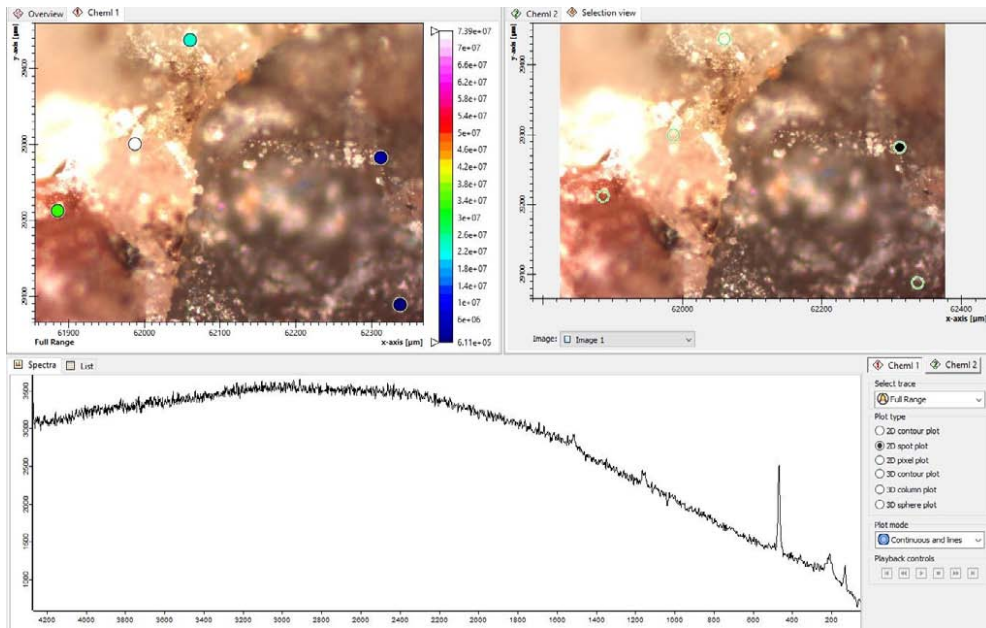

Note the fracture patterns on the microscopic image.

Sample:

Sample Site **20**: Stone 4_spectra 1 indicates: **Quartz** (→ see RRUFF_CS results)

Sample :

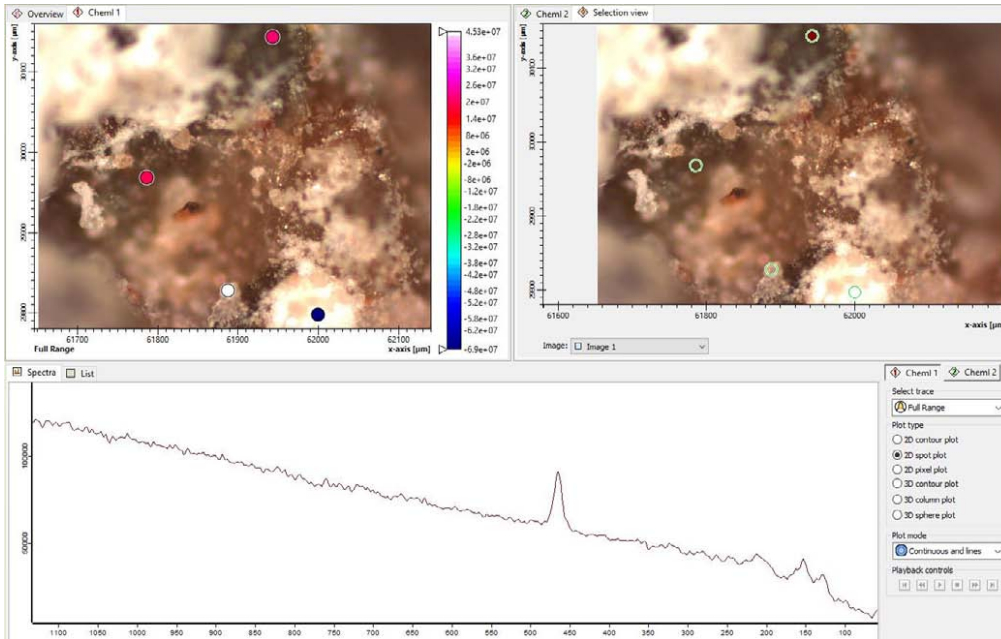

Indication for a shock event is the shift of the marked Quartz spectral lines towards 205

The spectral line 205 indicates that the Quartz was exposed to a **shock pressure of around 20 – 22 GPa.**

Sample Site **20**: Stone 5_spectra 1 indicates: **Quartz** (→ see RRUFF_CS results)

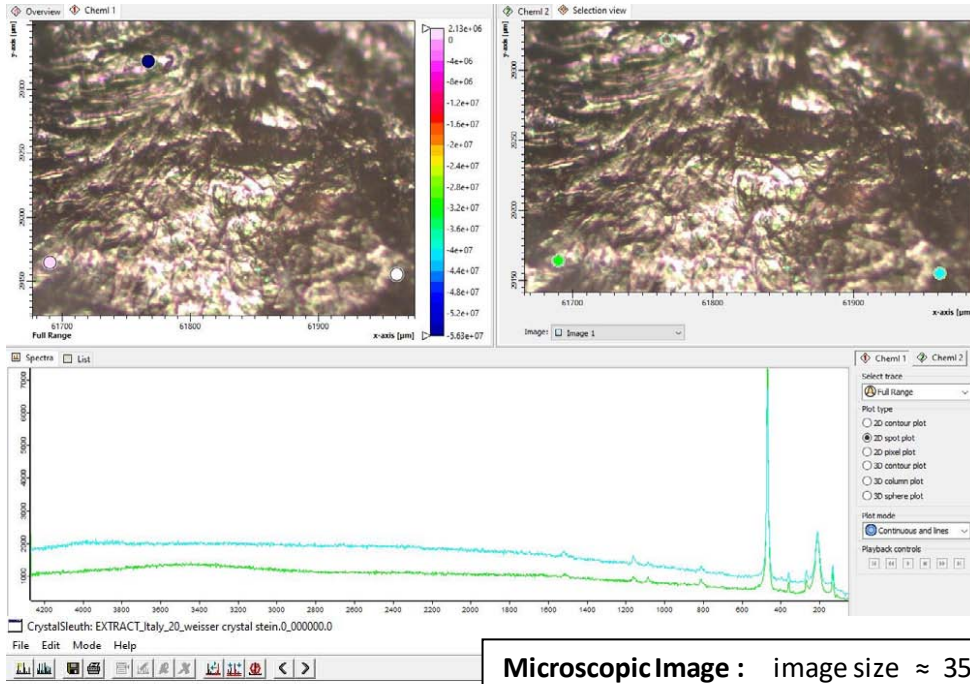

Sample :

Indication for a shock event is the shift of the marked Quartz spectral lines towards 263

Sample Site 20 : Stone 6_spectra 1 indicates: **Quartz** (→ see RRUFF_CS results)

Sample :

Appendix 2 : A short overview : The Raman bands (peaks) of Quartz shocked with 22-26 GPa

In order to verify a sample site as an impact site or impact structure, [shock-metamorphic effects](#) must be discovered in the rocks of the sample site. This can be done by different methods.

For example with the help of PDFs (planar deformation features) which are visible in the quartz with the help of a microscope. However this requires careful preparation of the samples and expertise.

Another, easier method, is the use of a RAMAN microscope. Micro-RAMAN Spectroscopy on quartz grains in the samples can provide the first evidence for a shock event, that was caused by an impact.

Mc Millan et al. (1992) and others have shown that the main RAMAN-peaks of Quartz shift towards lower frequencies if the Quartz was exposed the a shock-pressure > 15 GPa. → see diagram below

The shift of the main quartz RAMAN-peaks can be used to identify quartz that was shocked by an impact

Quartz shocked with 22 GPa and 26 GPa shows shifts of the main RAMAN-peaks of 1 - 4 cm⁻¹ to lower frequencies

Appendix 3 : Raman spectra of (W) weakly-shocked & (M) moderately-shocked Alkali-Feldspar

Weakly shocked alkali feldspar mainly developed irregular fractures and undulatory extinction. Note that the Raman-lines 210 and 765 are missing in the w-shocked feldspar, and an additional line at ≈ 150 appears.

The shock pressure for the w-shocked feldspar was estimated to be between 5 and 14 GPa
