

The Ø 30 km Mt Warning Impact Crater & 1.5 km Impact Crater (East-Australia)

- RAMAN Spectra of selected Rock Samples - by Harry K. Hahn , 30.6.2021 -

Summary :

Raman spectra of quartz from the sample sites **8-B2**, **8-B3** and **15-B** and **15-C** provide evidence for an impact scenario in the Mt Warning area in East-Australia. The Ø 30 km crater-shaped Mt Warning area and a smaller \approx Ø 1.5 km circular crater structure, which is located directly near the crater-rim of the Mt Warning Crater, seem to belong to a large-scale impact event caused by the Ø 320 km Cape York Crater in NE-Australia → see: [The 320 km Cape York Crater \(link2\)](#) & [Evidence for the Cape York Crater \(link4\)](#)

The possible Ø 320 km Cape York Crater belongs to a Secondary Impact Crater Chain along the NE-coast of Australia which was caused by ejecta from the Ø 1270 x 950 km Permian Triassic Crater in the Arctic Sea. According to the current geological theory Mount Warning is a strongly eroded shield volcano.

Referring to my Permian-Triassic Impact Hypothesis Mt Warning is the result of an impact of a big ejecta fragment from the Cape York Crater or from the PT-Impact Crater, which caused this Ø 30 km secondary crater that fractured Earth's crust and resulted in the growth of a large shield volcano above the crater

→ see my Permian Triassic Impact Hypothesis : [Part 1 \(P1\)](#), [Part 2 \(P2\)](#) & [Part 5 \(P5\)](#) → **Mars Impacts !**

The Raman spectra of quartz from sample site **8-B2**, on the foot of the crater-wall on the outside of the smaller Ø 1.5 km circular crater structure, provides **first evidence for an impact event !** (see Appendix)

The shifts of the main Raman bands (peaks) to the lower frequencies **463, 260, 205** and **127 cm^{-1}** which are visible in the Raman Spectra of the quartz-sample, clearly indicate that the quartz from this site was exposed to a **shock pressure of around 20 - 22 GPa**. (→ see explanation in the Appendix at [page 17](#)). The spectra were made with a **BRUKER Senterra-II Raman Microscope** (wavenumber precision $<0.1\text{cm}^{-1}$)

Further evidence comes from the quartz inclusions of rock sample **8-B3** from the same location.

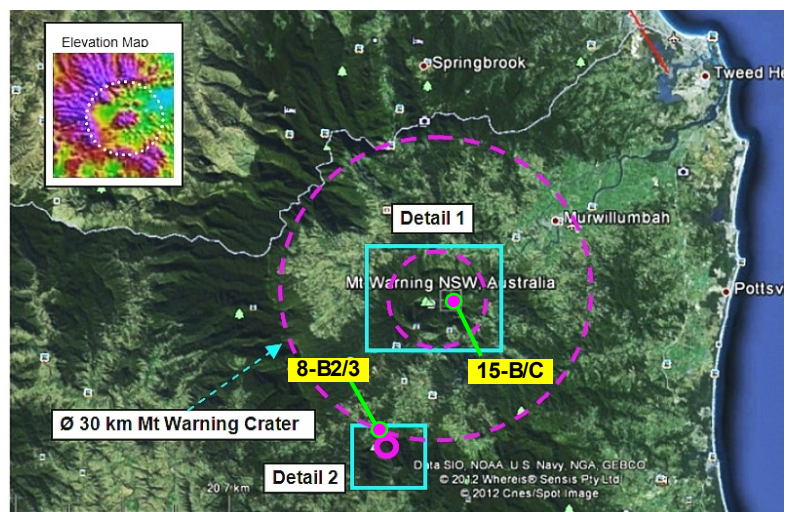

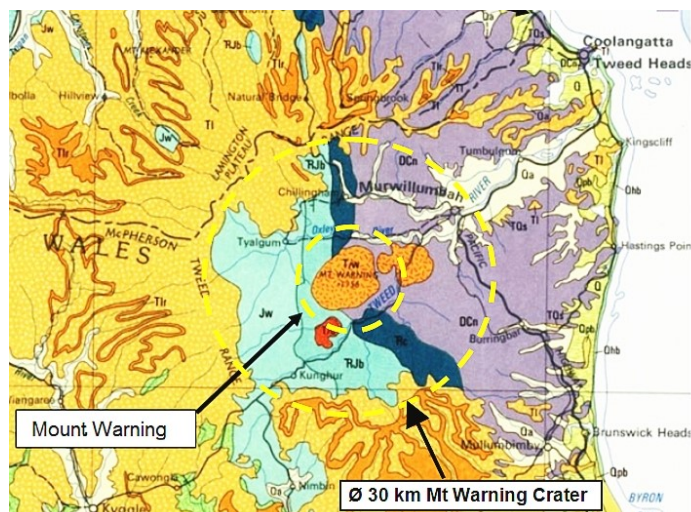

The shifts of the main Raman bands (peaks) to the lower frequencies **263** and **205 cm^{-1}** indicate the same **shock pressure of around 20 - 22 GPa**. The spectra of the rock samples from site **15-B** and **15-C**, the central mountain in the Mt Warning Crater, all indicate magmatic rocks which seems to confirm the formation of a volcano in the crater-center, in contrast to real impact-(wall)-structures on the crater-rim

A shock pressure of 20 GPa far exceeds every pressure caused by normal terrestrial metamorphism. Therefore the quartz was clearly shocked by an impact event. The indicated shock pressure of ≥ 20 GPa is lower than the shock pressure that occurred in other large impact craters on Earth, which can reach 100 GPa. This indicates that the Mt Warning Crater probably was caused by an oblique impact, and the impactor which formed the structure (ejecta of the CYC or PT-Crater) impacted with low velocity <8 km/s

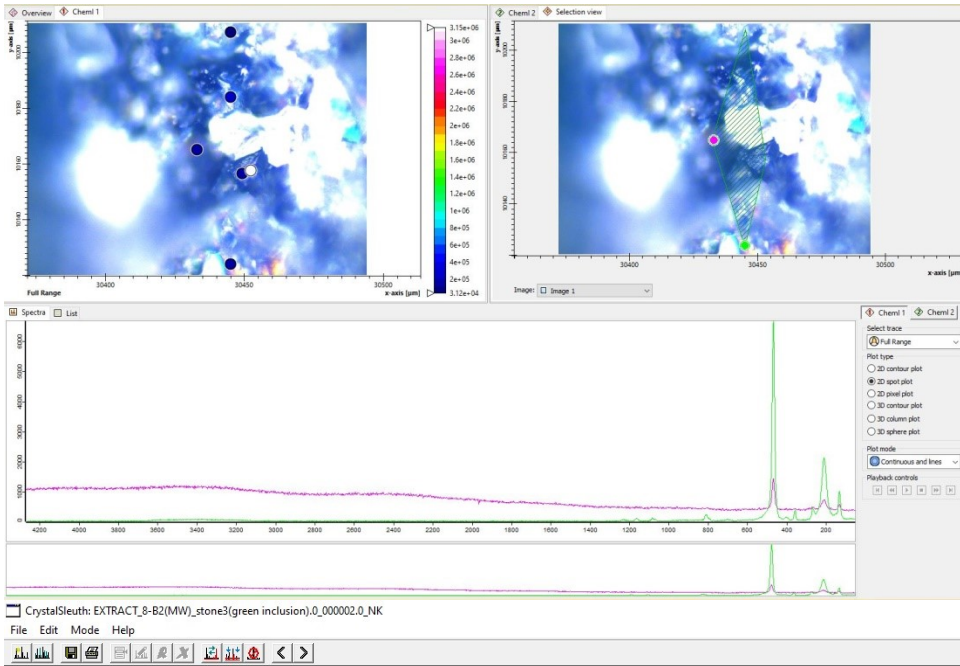

→ Images of the analysed rock samples and photos of the sample sites are in the Appendix at [page 12](#).

→ A general summary to all analysed sample sites is provided by [Part 6 \(P6\)](#) of my [PTI-hypothesis \(P1\)](#)

→ More images of all sample sites are available on www.permiantriassic.de or www.permiantriassic.at

Sample Site **8-B2** : Stone 3_spectra 2 (Green mineral inclusions) indicates: **Quartz** (→ RRUFF_CS results)

Sample :

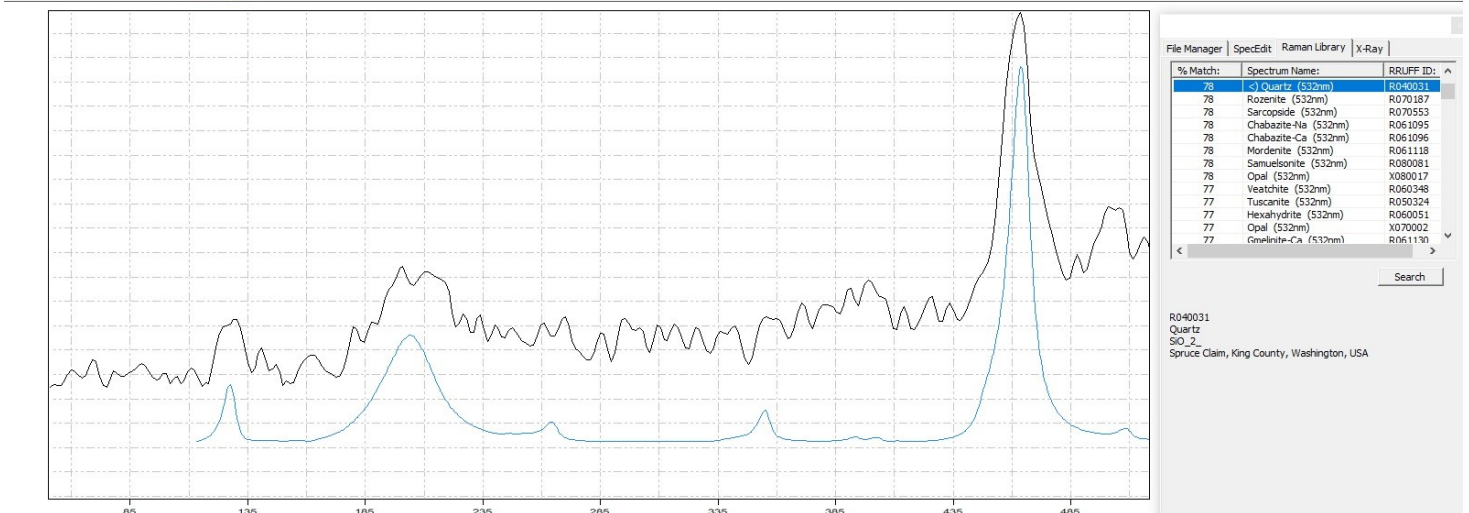

Indication for a shock event are the shifts of the marked Quartz spectral lines towards 463, 260, 205 and 127

Sample Site **8-B2** : Stone 2_spectra 1 indicates : **Quartz**. (→ see RRUFF_CS results)

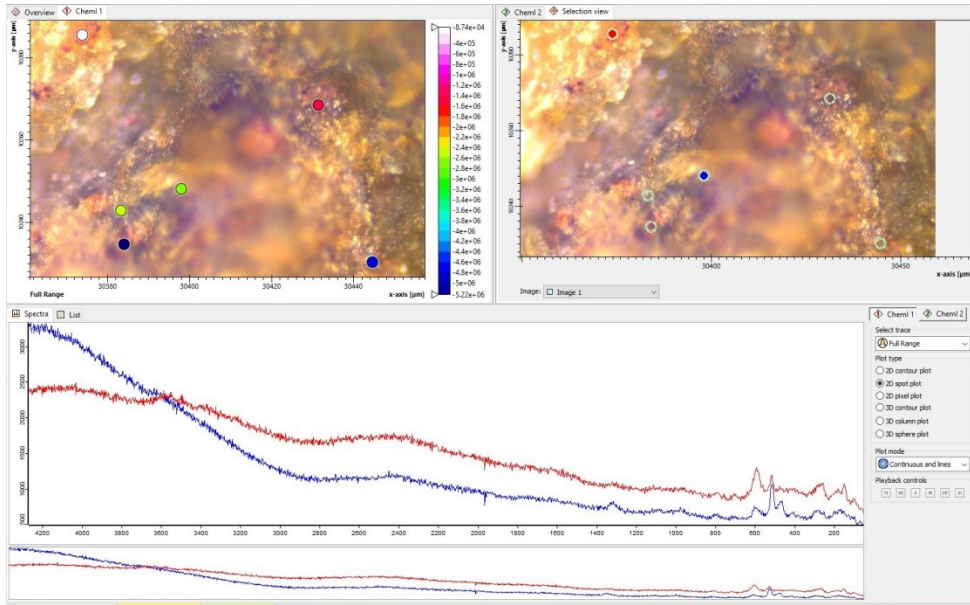

Sample :

Indication for a shock event is the shift of the marked main Quartz spectral line towards 463

Sample Site **8-B2** : Stone 3_spectra 1 (brown mineral) indicates : **Anorthoclase , Orthoclase** (→ RRUFF_CS)

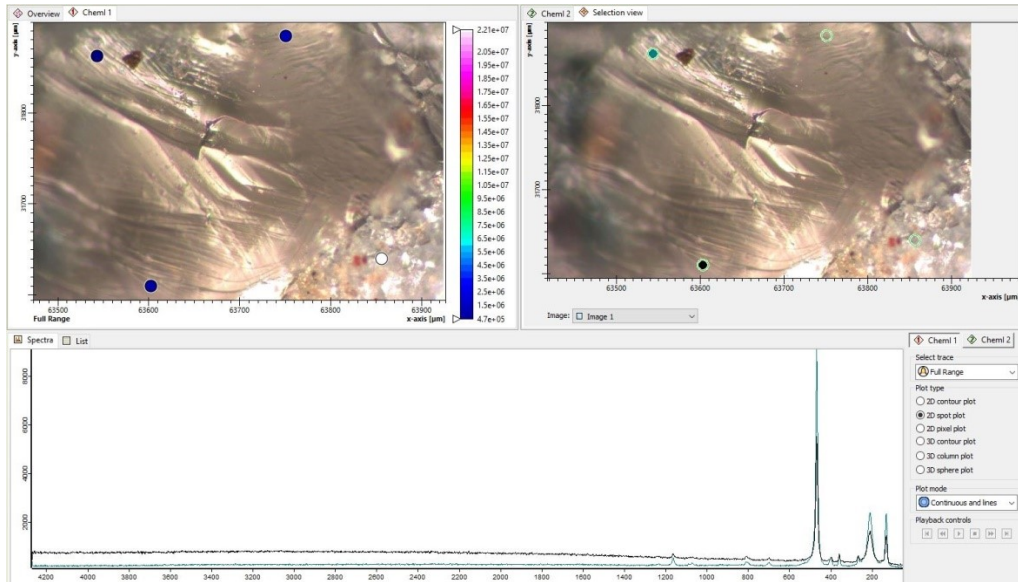

Sample :

spectrum indicates **weakly shocked alkali-feldspar** (shocked at least in the range $\geq 5 - 14$ GPa)

- missing of spectral-lines 210 & 765
- additional strong line at ≈ 150

Sample Site **8-B3** : Stone 1_spectra 1 (white mineral inclusions) indicates : **Quartz** (→ see RRUFF_CS results)

Sample :

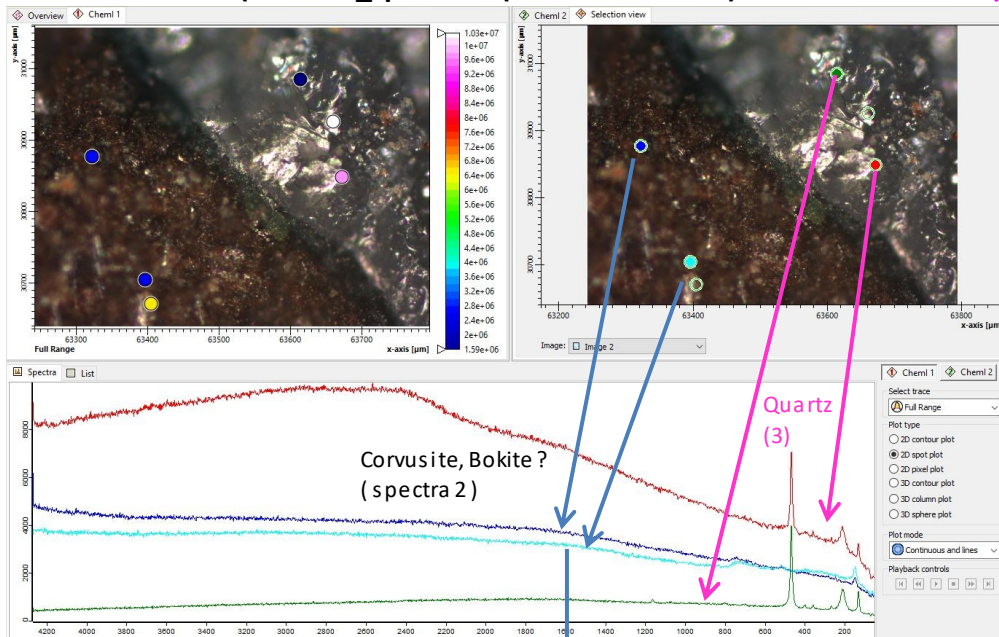

Indication for a shock event are the shifts of the marked Quartz spectral lines towards 263 and 205

Sample Site **8-B3** : Stone 1_spectra 2 (brown matrix) indicates : **Corvusite, Bokite** (→ see RRUFF_CS results)
 (Stone 1_spectra 3 (white inclusion) indicates : **Quartz**)

The image on the left shows the border-area between the brown matrix and one Quartz-inclusion

Sample Site **8-B2** : Stone 1_spectra 1 (green Mineral) indicates : (Orthoclase ? Quartz ?)

Spectra of poor quality contains to less information ! Therefore the result is only guesswork in this case.

Sample :

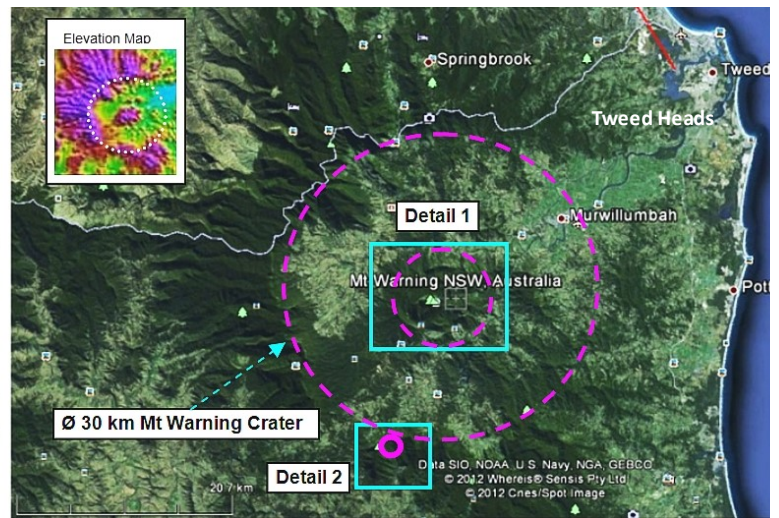

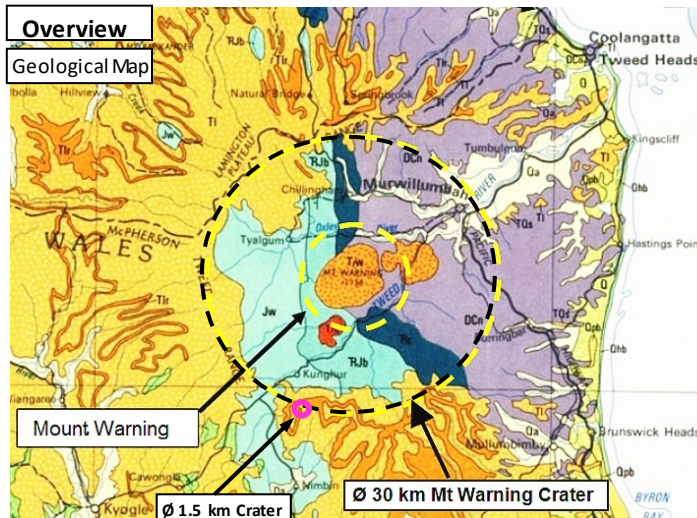

Note the green color

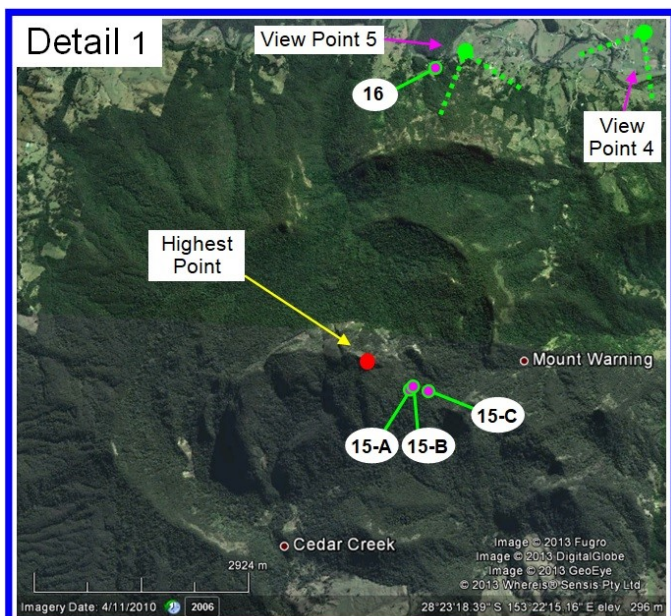

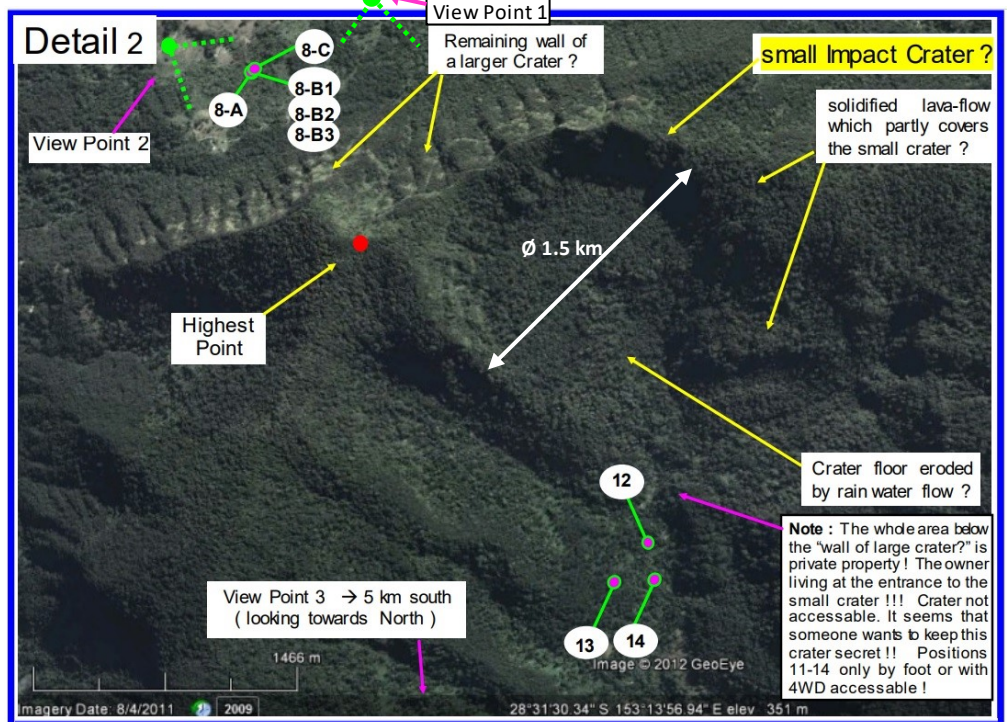

Appendix 1 : Photos of the rock samples from sample sites : 8-B2/-B3 and 15-A to 15-C
→ See next page !

Please note : Photos of Sample Sites [8-B2 /-B3](#) and [15-B](#) & [15-C](#) and other sample sites are also available here → weblink : [Sample Sites "Mt Warning Crater"](#)

Mount Warning is probably the result of a large **secondary impact** caused by the Cape York Impact Event, and is not the rest of an eroded shield-volcano as currently believed ! Therefore the age of the Mt Warning crater may be ~253 Ma. The chaotic looking central area of the Mt Warning crater (Detail 1) is probably the result of a shield volcano which grew on top of the Mt Warning impact crater after the Impact Event. When the volcanic activity ended, this shield volcano heavily eroded and collapsed into the visible chaotic structure. (Detail 1) consisting of magmatic material. Only the original Crater-wall of the Mt Warning crater is left from the original earlier impact event.

To the samples 8-B2/3 and 15-B/C :

The samples [8-B2](#) and [8-B3](#) were collected on the foot of a remaining section of the Ø 30 km Mt Warning crater.

This location lies close to the smaller Ø 1,5 km Crater, a bit below the level where the small crater is located. (→ see image above)

The samples [15-B](#) & [15-C](#) were collected on Mount Warning itself, which is the former top of the shield volcano (or top of the central uplift ?). It lies much deeper today because the shield volcano (which grew on top of the impact crater) eroded heavily and only left behind the former top of the volcano (or central uplift).

→ **Please find all images of all sample sites on my**

Note: permission may be required to do a geological expedition to the sites 8-B2/B3, located on private property

The probable crater-wall of Mt Warning Crater

Note the steep inclination of the strata (rock layers) which form the rock wall

View Point 1

Note : permission may be required to do a geological expedition to the sites 8-B2/B3, located on private property

Note: The sample sites 15-A to 15-C are accesible over a walking track (hiking trail). It's around a 1 hour walk.

Mount Warning

8-B3

8-B3 | 28° 30.972 S | 153° 12.483 E | 9 m | Mt Warning

Appendix 2 : A short overview : The Raman bands (peaks) of Quartz shocked with 22-26 GPa

In order to verify a sample site as an impact site or impact structure, [shock-metamorphic effects](#) must be discovered in the rocks of the sample site. This can be done by different methods.

For example with the help of PDFs (planar deformation features) which are visible in the quartz with the help of a microscope. However this requires careful preparation of the samples and expertise.

Another, easier method, is the use of a RAMAN microscope. Micro-RAMAN Spectroscopy on quartz grains in the samples can provide the first evidence for a shock event, that was caused by an impact.

Mc Millan et al. (1992) and others have shown that the main RAMAN-peaks of Quartz shift towards lower frequencies if the Quartz was exposed the a shock-pressure > 15 GPa. → see diagram below

The shift of the main quartz RAMAN-peaks can be used to identify quartz that was shocked by an impact

Quartz shocked with 22 GPa and 26 GPa shows shifts of the main RAMAN-peaks of 1 - 4 cm⁻¹ to lower frequencies

Appendix 3 : Raman spectra of (W) weakly-shocked & (M) moderately-shocked Alkali-Feldspar

Weakly shocked alkali feldspar mainly developed irregular fractures and undulatory extinction. Note that the Raman-lines 210 and 765 are missing in the w-shocked feldspar, and an additional line at ≈ 150 appears.

The shock pressure for the w-shocked feldspar was estimated to be between 5 and 14 GPa
